1 Properties

Definition 1. A property \mathbf{P} of linear orders is a class of linear orders which is closed under isomorphism.

Definition 2. A property \mathbf{P} of linear orders is monotone if for every linear order L , $L \in \mathbf{P}$ implies that every suborder of L is in \mathbf{P} .

Definition 3. A property \mathbf{P} of linear orders is symmetric if for every linear order L , $L \in \mathbf{P}$ iff $L^R \in \mathbf{P}$.

Definition 4. A property \mathbf{P} of linear orders is an additive property if for every linear orders L_1 and L_2 , $L_1 + L_2 \in \mathbf{P}$ iff $L_1, L_2 \in \mathbf{P}$.

Definition 5. A property \mathbf{P} of linear orders is a star property if for every family \mathcal{F} of linear orders in \mathbf{P} such that $\bigcap \mathcal{F} \neq \emptyset$, $\bigcup \mathcal{F} \in \mathbf{P}$.

Definition 6. Let \mathbf{P} be a property of linear orders.

We define **bounded** $-\mathbf{P}$ to be the class of linear orders L such that for every $x, y \in L$, the bounded subinterval $[x, y]$ is in \mathbf{P} .

Definition 7. A property \mathbf{P} of linear orders is almost anti-symmetric if for every linear order L , $L \in \mathbf{P}$ and $L^R \in \mathbf{P}$ imply that L is finite.

Lemma 1. Let \mathbf{P} be an additive property of linear orders.

Then the property **bounded** $-\mathbf{P}$ is has the star property.

2 Hausdorff Rank

Definition 8. Let \mathbf{Q} be a property of linear orders.

We define a property \mathbf{Q}^α for every ordinal α as follows:

Let L be a linear order.

We define $\mathbf{hrank}_{\mathbf{Q}}(L) \leq 0$ iff L is finite.

Let $\alpha > 0$ be an ordinal.

We define $\mathbf{hrank}_{\mathbf{Q}}(L) \leq \alpha$ iff $L = \sum_{i \in I} L_i$ for some linear order I , where $\mathbf{hrank}_{\mathbf{Q}}(L_i) < \alpha$ and I is a finite sum of 1 , ω and $-\omega$.

We write $\mathbf{hrank}_{\mathbf{Q}}(L) = \alpha$ iff α is the least ordinal such that $\mathbf{hrank}_{\mathbf{Q}}(L) \leq \alpha$.

We will be working with countable linear orders.

Claim 1. *Let L be a countable linear order.*

Then $\mathbf{hrank}_{\mathbf{Q}}(L)$ is defined iff L is scattered.

Proof. To prove \implies is easy, as a scattered sum of scattered linear orders is scattered.

For the other direction... TODO. □

Notations 1. *Let \mathcal{H}_α be the class of linear orders of Hausdorff rank $< \alpha$ and $\mathcal{H}_{=\alpha}$ be the class of linear orders of Hausdorff rank $= \alpha$.*

Let \mathcal{B}_α be the class of linear orders of Hausdorff rank $< \alpha$ on bounded subintervals.

Let $\mathcal{Q}_\alpha = \{L : 1 + L \in \mathcal{B}_\alpha\}$.

Let $\mathcal{R}_\alpha = \{L : L + 1 \in \mathcal{B}_\alpha\}$.

Clearly, $\mathcal{H}_\alpha, \mathcal{Q}_\alpha, \mathcal{R}_\alpha \subseteq \mathcal{B}_\alpha$.

Clearly, $\mathcal{H}_{\alpha+1} = \{L : \mathbf{hrank}_{\mathbf{Q}}(L) \leq \alpha\}$.

Claim 2. *The following are equal:*

1. \mathcal{H}_α
2. $\{L : 1 + L + 1 \in \mathcal{B}_\alpha\}$.
3. $\mathcal{Q}_\alpha \cap \mathcal{R}_\alpha$

Proof. The equivalence of 1 and 2 is clear, and obviously 2 implies 3.

The other direction (3 implies 2) follows from the star property of \mathcal{B}_α . □

Lemma 2. *Let L be a linear order. Then there exists a largest subinterval $M \subseteq L$ such that $x \in M$ and $M \in \mathcal{B}_\alpha$.*

Definition 9. *Let L be a linear order. Let $x \in L$. We define $M_\alpha[x]$ to be the largest subinterval $M \subseteq L$ such that $x \in M$ and $M \in \mathcal{B}_\alpha$.*

We define \sim_α to be the equivalence relation on L such that $x \sim_\alpha y$ iff $M_\alpha[x] = M_\alpha[y]$.

Lemma 3. *Let L be a linear order. Let $P, Q, R \subseteq L$ be relations, such that:*

- P represents \sim_α on L .
- Q is such that $x \in Q$ iff $M_\alpha[x] \in \mathcal{Q}_\alpha$.
- R is such that $x \in R$ iff $M_\alpha[x] \in \mathcal{R}_\alpha$.

Then for some linear order I there exists a decomposition $L = \sum_{i \in I} L_i$ such that $L_i \in \mathcal{B}_\alpha$ for all $i \in I$, L_i is monochromatic with respect to P , Q and R .

Furthermore, let τ_i be the n -type of L_i, p_i, q_i, r_i in $\mathbf{MSO}[p, q, r]$, where $p_i = 1_{L_i \subseteq P}$, $q_i = 1_{L_i \subseteq Q}$ and $r_i = 1_{L_i \subseteq R}$. Then the following hold

- *if i has a successor, $p(\tau_i) \neq p(\tau_{i+1})$*

- if i has a successor, either $r(\tau_i) = 0$ or $q(\tau_{i+1}) = 0$

Proof. Take $I = L / \sim_\alpha$.

Then $L = \sum_{i \in I} L_i$ where L_i is the \sim_α -equivalence class of i .

Then L_i is monochromatic with respect to P , Q and R .

The only thing left to prove is the last two conditions. The first follows from the fact that P represents \sim_α .

The second follows because if it were not the case, then L_i and L_{i+1} would be the same \sim_α -equivalence class. \square

Lemma 4. *Let I be a linear order. Let $n \in \mathbb{N}$. Let p, q, r be boolean variables.*

Let τ_i be an assignment of satisfiable n -types in $\mathbf{MSO}[p, q, r]$ for all $i \in I$. Assume that

- if i has a successor, $p(\tau_i) \neq p(\tau_{i+1})$
- if i has a successor, either $r(\tau_i) = 0$ or $q(\tau_{i+1}) = 0$

Then there exists a linear order L and $P, Q, R \subseteq L$ such that:

- P represents \sim_α on L .
- Q is such that $x \in Q$ iff $M_\alpha[x] \in \mathcal{Q}_\alpha$.
- R is such that $x \in R$ iff $M_\alpha[x] \in \mathcal{R}_\alpha$.

such that for all $i \in I$, L_i is a \sim_α -equivalence class of L , and is thus monochromatic with respect to P , Q and R .

Furthermore, the n -type of L_i, p_i, q_i, r_i in $\mathbf{MSO}[p, q, r]$ is τ_i , where $p_i = 1_{L_i \subseteq P}$, $q_i = 1_{L_i \subseteq Q}$ and $r_i = 1_{L_i \subseteq R}$,

Proof. Since τ_i is satisfiable, we can take L_i to be a linear order of n -type τ_i such that:

- If $q(\tau_i) = r(\tau_i) = 1$, then $L_i \in \mathcal{Q}_\alpha \cap \mathcal{R}_\alpha$.
- If $q(\tau_i) = 1$ and $r(\tau_i) = 0$, then $L_i \in \mathcal{Q}_\alpha - \mathcal{R}_\alpha$.
- If $q(\tau_i) = 0$ and $r(\tau_i) = 1$, then $L_i \in \mathcal{R}_\alpha - \mathcal{Q}_\alpha$.
- If $q(\tau_i) = r(\tau_i) = 0$, then $L_i \in \mathcal{B}_\alpha - (\mathcal{Q}_\alpha \cup \mathcal{R}_\alpha)$.

Let $L = \sum_{i \in I} L_i$.

By definition each L_i is in \mathcal{B}_α . We need to prove that each L_i is a largest \mathcal{B}_α -subinterval in L .

On the contrary, suppose that there exist $i' \neq i$ such that $[L_i, L_{i'}] \in \mathcal{B}_\alpha$. WLOG, $L_i < L_{i'}$.

Since I is scattered, take some $i \leq a < b \leq i'$ such that there is no element between a and b in I .

Then $L_a \in \mathcal{R}_\alpha$ and $L_b \in \mathcal{Q}_\alpha$, in contradiction. \square

Lemma 5. *Let L be a countable linear order.*

Let $J \subseteq L$ be some subinterval in \mathcal{B}_α .

Then $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$.

Furthermore, $\mathbf{hrank}_\mathbf{Q}(J) < \alpha$ iff $J \in \mathcal{Q}_{<\alpha} \cap \mathcal{R}_{<\alpha}$.

Proof. Let $\{x_i\}_{i \in I} \subseteq J$ be a bidirectional, cofinal, weakly monotone I -sequence in J , i.e, $x_i \leq x_j$ if $i \leq j$ for $I \subseteq \mathbb{Z}$.

Write $J = \sum_{i \in I} [x_i, x_{i+1}]$. Then every $[x_i, x_{i+1}]$ is of Hausdorff rank $< \alpha$.

Thus, $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$.

Suppose $\mathbf{hrank}_\mathbf{Q}(J) < \alpha$, then obviously $J \in \mathcal{Q}_{<\alpha} \cap \mathcal{R}_{<\alpha}$.

Conversely, suppose $J \in \mathcal{Q}_{<\alpha} \cap \mathcal{R}_{<\alpha}$.

Then $1+J+1 \in \mathcal{B}_\alpha$. But it is a bounded interval, so $\mathbf{hrank}_\mathbf{Q}(1+J+1) < \alpha$ and thus $\mathbf{hrank}_\mathbf{Q}(J) < \alpha$. \square

Lemma 6. *Let $J \subseteq L$ be a subinterval.*

Then $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$ iff J is a finite sum of \mathcal{B}_α -subintervals.

Note: this lemma does not work if we take a general \mathbf{Q} property.

Proof. From the previous lemma, it is clear that if J is a finite sum of \mathcal{B}_α -subintervals, then $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$, since the rank bound is preserved under finite sums.

Conversely, suppose $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$.

If $J = \sum_{i \in \mathbb{Z}} J_i$ for some J_i of Hausdorff rank $< \alpha$, take $x, y \in J$. Then let $x \in J_{i_1}$ and $y \in J_{i_2}$.

Then $[x, y] \subseteq \sum_{i \in [i_1, i_2]} J_i$. But the last sum is of rank $< \alpha$ and thus $[x, y]$ is of rank $< \alpha$. That is, $J \in \mathcal{B}_\alpha$.

Since every subinterval of rank $\leq \alpha$ is a finite sum of \mathbb{Z} -sums of intervals of rank $< \alpha$, we are done. \square

Corollary 1. *Let $J \subseteq L$ be a subinterval.*

Then $\mathbf{hrank}_\mathbf{Q}(J) \leq \alpha$ iff J is a finite sum of largest \mathcal{B}_α -subintervals in L

Lemma 7. *There exists a global computable function $f : \mathbb{N} \rightarrow \mathbb{N}$ such that for all $n \in \mathbb{N}$, $\mathbf{type}_n[\mathcal{H}_{f(n)+1}] = \mathbf{type}_n[\mathcal{H}_{f(n)}]$.*

Equivalently, every linear order of finite rank is n -equivalent to some linear order of rank $\leq f(n)$.

Proof. Since there exist only a finite number of n -types, and the ω -sequence $\{\mathbf{type}_n[\mathcal{H}_k]\}_{k \in \omega}$ is monotone, it must stabilize at some point.

This point is computable as a function of n , because $\mathbf{type}_n[\mathcal{H}_k]$ is computable for every finite k . \square

Lemma 8. *There exist global computable functions $a, b : \mathbb{N} \rightarrow \mathbb{N}$ such that for all $n, c_1, c_2 \in \mathbb{N}$ such that $c_1, c_2 \geq a(n)$ and $c_1 \equiv c_2 \pmod{b(n)}$,*

$$\mathbf{type}_n[\mathcal{H}_{c_1}] = \mathbf{type}_n[\mathcal{H}_{c_2}]$$

Equivalently, the sequence $\{\mathbf{type}_n[\mathcal{H}_k]\}_{k \in \omega}$ is ultimately periodic for all $n \in \mathbb{N}$. Furthermore, the starting point and the period itself can be computed as a function of n .

Proof. Let $n \in \mathbb{N}$.

Since there exist only a finite number of possible sets of n -types, there exist (and can be computed) some $a(n) > f(n)$, $a(n) + b(n)$ such that

$$\mathbf{type}_n[\mathcal{H}_{a(n)}] = \mathbf{type}_n[\mathcal{H}_{a(n)+b(n)}]$$

We shall prove by induction that for all $c \geq a(n) + b(n)$,

$$\mathbf{type}_n[\mathcal{H}_c] = \mathbf{type}_n[\mathcal{H}_{c+b(n)}]$$

This will complete the proof.

The base case $c = a(n)$ has been proven in the beginning.

Suppose the induction hypothesis holds for c .

Let L be of rank $c + 1$.

Write $L = \sum_{i \in I} L_i$ where $\mathbf{hrank}_{\mathbf{Q}}(L_i) < c + 1$, and $\mathbf{hrank}_{\mathbf{Q}}(L_i) = c$ infinitely many times.

By the induction hypothesis, if $\mathbf{hrank}_{\mathbf{Q}}(L_i) = c$, we can find $N_i \equiv_n L_i$ with $\mathbf{hrank}_{\mathbf{Q}}(N_i) = c + b(n)$. Setting $N_i := L_i$ for all other i , we conclude that $N := \sum_{i \in I} N_i$ is n -equivalent to L .

However, clearly $\mathbf{hrank}_{\mathbf{Q}}(N) = c + b(n) + 1$. So overall,

$$\mathbf{type}_n[\mathcal{H}_{c+1}] \subseteq \mathbf{type}_n[\mathcal{H}_{c+b(n)+1}]$$

Conversely, suppose L is of rank $c + b(n) + 1$. Write $L = \sum_{i \in I} L_i$ where $\mathbf{hrank}_{\mathbf{Q}}(L_i) < c + b(n) + 1$, and $\mathbf{hrank}_{\mathbf{Q}}(L_i) = c + b(n)$ infinitely many times.

By the induction hypothesis, we can find for all i such that $\mathbf{hrank}_{\mathbf{Q}}(L_i) = c + b(n)$ some $N_i \equiv_n L_i$ with $\mathbf{hrank}_{\mathbf{Q}}(N_i) = c$. Furthermore, since $c \geq a(n) > f(n)$, we can find $N_i \equiv_n L_i$ with $\mathbf{hrank}_{\mathbf{Q}}(N_i) \leq f(n) < c$ for all other i .

We conclude that $N := \sum_{i \in I} N_i$ is n -equivalent to L . However, clearly $\mathbf{hrank}_{\mathbf{Q}}(N) = c + 1$. So overall,

$$\mathbf{type}_n[\mathcal{H}_{c+b(n)+1}] \subseteq \mathbf{type}_n[\mathcal{H}_{c+1}]$$

So we have proven the induction step, and the lemma follows. \square

Lemma 9. Let $n \in \mathbb{N}$, and let $\alpha \geq \omega$ be an ordinal.

Then,

$$\mathbf{type}_n[\mathcal{H}_\alpha] = \bigcup_{c < b(n)} \mathbf{type}_n[\mathcal{H}_{c+b(n)}]$$

In particular, $\mathbf{type}_n[\mathcal{H}_\alpha]$ can be computed, and is independent of the choice $\alpha \geq \omega$.

Proof. TBC. \square

Proof. By induction on $\alpha \geq f(n)$ suppose that for all $f(n) \leq \beta < \alpha$,

$$\mathbf{type}_n[\mathcal{H}_{\beta+1}] = \mathbf{type}_n[\mathcal{H}_{f(n)}]$$

Let L be a scattered linear order of rank α .

Then $L = \sum_{i \in I} L_i$ where $\mathbf{hrank}_{\mathbf{Q}}(L_i) < \alpha$. By the induction hypothesis, we can find $N_i \equiv_n L_i$ with $\mathbf{hrank}_{\mathbf{Q}}(N_i) < f(n)$.

Let $N = \sum_{i \in I} N_i$. Then $L \equiv_n N$.

Additionally, $\mathbf{hrank}_{\mathbf{Q}}(N) < f(n) + 1$ by the rank definition. However, that means that we can find $N' \equiv_n N$ with $\mathbf{hrank}_{\mathbf{Q}}(N') \leq f(n)$ by the definition of $f(n)$. \square

Corollary 2. *The following sequences stabilize at $f(n)$:*

- $\mathbf{type}_n[\mathcal{H}_\alpha]$
- $\mathbf{type}_n[\mathcal{B}_\alpha]$
- $\mathbf{type}_n[\mathcal{Q}_\alpha]$
- $\mathbf{type}_n[\mathcal{R}_\alpha]$
- $\mathbf{type}_n[\mathcal{Q}_\alpha - \mathcal{R}_\alpha]$
- $\mathbf{type}_n[\mathcal{R}_\alpha - \mathcal{Q}_\alpha]$
- $\mathbf{type}_n[\mathcal{B}_\alpha - (\mathcal{Q}_\alpha \cup \mathcal{R}_\alpha)]$

Proof. Let A_k be the set of all satisfiable n -types of rank $< k$. Then A_{k+1} is the closure of A_k under finite sums of $\subseteq \mathbb{Z}$ -sums.

The sequence $A_0 \subseteq A_1 \subseteq \dots$ stabilizes at some point. Suppose $A_{f(n)} = A_{f(n)+1}$.

Suppose L has rank $\beta \geq f(n)$.

Write $L = \sum_{i \in I} L_i$ where $\mathbf{hrank}_{\mathbf{Q}}(L_i) < \beta$, and I is a finite sum of $\subseteq \mathbb{Z}$.

If β is a limit ordinal, then there must be a bi-cofinal sequence i_k such that $\mathbf{hrank}_{\mathbf{Q}}(L_{i_k}) \rightarrow \beta$.

If β is a successor ordinal, then $\mathbf{hrank}_{\mathbf{Q}}(L_i) = \beta - 1$ must hold infinitely many times.

Now we proceed by induction on $\alpha \geq f(n)$.

1. If $\mathcal{C} = \mathcal{H}_\alpha$, we take $L' \in A_{f(n)}$, which necessarily has rank $< f(n) \leq \alpha$.
2. If $\mathcal{C} = \mathcal{Q}_\alpha - \mathcal{R}_\alpha$, we take an ω -sequence α_k such that $\alpha_k \rightarrow \alpha$ (if α is a limit ordinal) or $\alpha_k = \alpha - 1$ (if α is a successor ordinal).
Then we take $L' = \sum_{i \in \omega} L'_i$ where $\mathbf{hrank}_{\mathbf{Q}}(L'_{i_k}) = \alpha_k$ (and $\mathbf{hrank}_{\mathbf{Q}}(L'_i) = \mathbf{hrank}_{\mathbf{Q}}(L_i)$ for every other i). Then $L' \in \mathcal{Q}_\alpha - \mathcal{R}_\alpha$, but also $L' \equiv_n L$.
3. This is just the same with $-\omega$ instead of ω .
4. This is just the same with \mathbb{Z} instead of $-\omega$.

\square

Corollary 3. *Over countable linear orders with interpretations of P , Q and R as above, the properties $\mathbf{hrank}_{\mathbf{Q}}(\cdot) \leq \alpha$, $\mathbf{hrank}_{\mathbf{Q}}(\cdot) < \alpha$ and $\mathbf{hrank}_{\mathbf{Q}}(\cdot) = \alpha$ over subintervals are all expressible in $\mathbf{MSO}[P, Q, R]$.*

Proof. For $\mathbf{hrank}_Q(\cdot) \leq \alpha$ and $\mathbf{hrank}_Q(\cdot) < \alpha$, we can use the previous lemmas.

For $\mathbf{hrank}_Q(\cdot) = \alpha$, we can use the previous two. \square

Theorem 1. *There is an algorithm solving satisfiability for $\mathbf{MSO}[P, Q, R]$ over countable linear orders, given an oracle which solves the satisfiability problem for \mathbf{MSO} over countable linear orders.*

Proof. By the decomposition theorem, there exists a translation, that given an $\mathbf{MSO}[P, Q, R]$ formula φ of quantifier-depth n , outputs an $\mathbf{MSO}[\{X_\tau\}_\tau]$ formula ψ .

Let P_L, Q_L, R_L be the interpretations of P, Q, R on L .

Then

$$L, P := P_L, Q := Q_L, R := R_L \models \varphi \iff I, \{X_\tau := I_\tau\}_\tau \models \psi$$

Where $I_\tau = \{i \in I : L_i \models \tau\}$ for every n -type τ .

Let T be the set of n -types in $\mathbf{MSO}[p, q, r]$ which satisfy $q(\tau) = 1 \iff \tau \in \mathcal{Q}_\alpha$ and $r(\tau) = 1 \iff \tau \in \mathcal{R}_\alpha$.

Let $S = \{(\tau_1, \tau_2) : p(\tau_1) \neq p(\tau_2) \wedge (r(\tau_1) = 0 \vee q(\tau_2) = 0)\}$.

Then T and S can be calculated using the oracle.

Then ψ is an $\mathbf{MSO}[T, S]$ formula.

Then we define an $\mathbf{MSO}[p, q, r]$ formula ψ' as follows:

ψ' claims that there exists a partition (with possible empty sets) $\{Y_\tau\}_\tau$ of I such that

- Every $i \in I$ is in some Y_τ for $\tau \in T$.
- If $i' = i + 1$ in I , then for some $(\tau_1, \tau_2) \in S$, $i \in Y_{\tau_1}$ and $i' \in Y_{\tau_2}$.

Now we claim that φ is satisfiable in some linear order, iff ψ' is satisfiable in some linear order.

Suppose φ is satisfiable in some linear order L .

Take a decomposition $L = \sum_{i \in I} L_i$ as in lemma 2.

Then ψ holds over the assignment $X_\tau := I_\tau$. But by lemma 2, this assignment satisfies the condition required for ψ' to hold. Then ψ' holds over I .

Conversely, suppose ψ' holds in I .

Let $X_\tau := Z_\tau$ be the assignment that is guaranteed by ψ' .

Let τ_i be the unique τ such that $i \in Z_\tau$.

Then the conditions for lemma 3 are guaranteed.

Thus, take L as in lemma 3. Then ψ holds over I when we set $X_i := Z_{\tau_i}$.

But $Z_\tau = I_\tau$ for all τ , so φ holds over L . \square
