## 1 Properties

**Definition 1.** A property P of linear orders is a class of linear orders which is closed under isomorphism.

**Definition 2.** A property  $\mathbf{P}$  of linear orders is monotone if for every linear order M,  $M \in \mathbf{P}$  implies that every suborder of M is in  $\mathbf{P}$ .

**Definition 3.** A property **P** of linear orders is symmetric if for every linear order M,  $M \in \mathbf{P}$  iff  $M^R \in \mathbf{P}$ .

**Definition 4.** A property **P** of linear orders is an additive property if for every linear orders  $M_1$  and  $M_2$ ,  $M_1 + M_2 \in \mathbf{P}$  iff  $M_1, M_2 \in \mathbf{P}$ .

**Definition 5.** Let **P** be a property of linear orders.

We define **P-bounded** to be the class of linear orders M such that for every  $x, y \in M$ , the bounded subinterval [x, y] is in **P**.

**Definition 6.** A property **P** of linear orders is almost anti-symmetric if for every linear order M,  $M \in \mathbf{P}$  and  $M^R \in \mathbf{P}$  imply that M is finite.

**Definition 7.** A property **P** of linear orders is good if it is monotone, additive and contains at least one infinite linear order.

**Definition 8.** A property  $\mathbf{P}$  of linear orders is a star property if for every linear orders M, and every family  $\mathcal{F} \subseteq \mathbf{P}$  of subintervals of M such that  $J_1 \cap J_2 \neq \emptyset$  for every  $J_1, J_2 \in \mathcal{F}$ , we have that  $\bigcup \mathcal{F} \in \mathbf{P}$ .

**Lemma 1** (Star Lemma). Let **P** be an additive property of linear orders. Then the property **P-bounded** has the star property.

*Proof.* Let M be a linear order, and let  $\mathcal{F} \subseteq \mathbf{P}$ -bounded be a family of subintervals of M.

Let  $[x, y] \subseteq \bigcup \mathcal{F}$  be any bounded subinterval. We need to prove it is in **P**. Suppose  $x \in J_1$  and  $y \in J_2$  for  $J_1, J_2 \in \mathcal{F}$ .

Since  $J_1 \cap J_2 \neq \emptyset$ , we can take  $z \in J_1 \cap J_2$ .

Then  $[x, z] \subseteq J_1$  and  $[z, y] \subseteq J_2$ , and thus by **P-bounded**,  $[x, z], [z, y] \in \mathbf{P}$ . However, **P** is additive. Since [x, y] is either the sum or difference of [x, z] and [z, y], we have that  $[x, y] \in \mathbf{P}$ . Lemma 2. Let P be a star property.

Then for every linear order M, and every point  $x \in M$ , there exists a largest subinterval  $J \subseteq M$  such that  $J \in \mathbf{P}$ .

Thus, we can define an equivalence relation  $\sim_{\mathbf{P}}$  on M such that  $x \sim_{\mathbf{P}} y$  iff x and y are in the same largest **P**-subinterval.

*Proof.* Let  $J \subseteq M$  be the union of all **P-bounded**-subintervals containing x. All such subintervals intersect at x.

Therefore, by the star lemma, J is in **P-bounded**, and by definition J is the largest **P**-subinterval containing x.

Thus we can define the equivalence relation  $\sim_{\mathbf{P}}$  as above.

#### 2 Hausdorff Rank

**Definition 9.** Let **Q** be a good property of linear orders. We define a property  $\mathbf{Q}^{\leq \alpha}$  for every ordinal  $\alpha$  as follows:

- $\mathbf{Q}^{\leq 0}$  is the class of finite linear orders.
- For  $\alpha > 0$ ,  $\mathbf{Q}^{\leq \alpha}$  is the class of linear orders M such that  $M = \sum_{i \in I} M_i$ for some  $I \in \mathbf{Q}$  where for all  $i \in I$ ,  $M_i \in \mathbf{Q}^{\beta_i}$  for some  $\beta_i < \alpha$

We define further  $\mathbf{Q}^{<\alpha} = \bigcup_{\beta < \alpha} \mathbf{Q}^{\leq \beta}$  and  $\mathbf{Q}^{=\alpha} = \mathbf{Q}^{\leq \alpha} - \mathbf{Q}^{<\alpha}$ . We define  $\mathbf{hrank}_{\mathbf{Q}}(M) = \alpha$  iff  $M \in \mathbf{Q}^{=\alpha}$ . This is a partial map from linear orders to ordinals.

Observations 1. Let Q be a good property.

We claim the following without proof:

- $\mathbf{Q}^{\leq 1} = \mathbf{Q}$ .
- For all  $\alpha$ ,  $\mathbf{Q}^{\leq \alpha}$  is a good property.
- $\mathbf{Q}^{\leq \alpha} \subseteq \mathbf{Q}^{\leq \beta}$  iff  $\alpha < \beta$ .

**Definitions 1.**  $\mathcal{B}_{<\alpha} := \mathbf{Q}^{<\alpha}$ -bounded is the class of linear orders of rank  $< \alpha$ on bounded intervals.

 $\mathcal{R}_{<\alpha}$  is the class of linear orders M where  $M+1 \in \mathcal{B}_{<\alpha}$ .  $\mathcal{L}_{\leq \alpha}$  is the class of linear orders M where  $1 + M \in \mathcal{B}_{\leq \alpha}$ .

Claim 1. The following are equal:

- 1.  $\mathbf{Q}^{<\alpha}$
- 2.  $\{M: 1+M+1 \in \mathcal{B}_{<\alpha}\}$ .
- 3.  $\mathcal{L}_{<\alpha} \cap \mathcal{R}_{<\alpha}$

*Proof.* The only nontrivial direction is 3 implies 2, which follows from the star property of  $\mathcal{B}_{<\alpha}$ .  **Lemma 3.** A countable linear order which has rank  $< \alpha$  on bounded subintervals is of rank  $\le \alpha$ . That is,

$$\mathcal{B}_{<\alpha} \subseteq \mathbf{Q}^{\leq \alpha}$$

*Proof.* Let M be a countable linear order of rank  $< \alpha$ .

Then  $M = \sum_{i \in I} M_i$  where  $M_i \in \mathbf{Q}^{<\alpha}$ .

Let  $\{x_i\}_{i\in I}\subseteq M$  be a bidirectional, cofinal, weakly monotone I-sequence in M, i.e,  $x_i\leq x_j$  if  $i\leq j$  for  $I\subseteq \mathbb{Z}$ .

Write  $M = \sum_{i \in I} [x_i, x_{i+1}]$ . Then every  $[x_i, x_{i+1}]$  is of Hausdorff rank  $< \alpha$ . Thus,  $\mathbf{hrank}_{\mathbf{Q}}(M) \le \alpha$ , which completes the proof.

Lemma 4. Let M be a countable linear order.

Then  $\mathbf{hrank}_{\mathbf{Q}}(M) \leq \alpha$  iff M is a finite sum of  $\mathcal{B}_{<\alpha}$ -subintervals.

Note: this lemma does not work if we take a general **Q** property.

*Proof.* From the previous lemma, it is clear that if M is a finite sum of  $\mathcal{B}_{<\alpha}$ -subintervals, then  $\mathbf{hrank}_{\mathbf{Q}}(M) \leq \alpha$ , since the rank bound is preserved under finite sums.

Conversely, suppose  $\mathbf{hrank}_{\mathbf{Q}}(M) \leq \alpha$ .

If  $M = \sum_{i \in \mathbb{Z}} M_i$  for some  $M_i$  of Hausdorff rank  $< \alpha$ , take  $x, y \in M$ . Then let  $x \in M_{i_1}$  and  $y \in M_{i_2}$ .

Then  $[x,y] \subseteq \sum_{i \in [i_1,i_2]} M_i$ . But the last sum is of rank  $< \alpha$  and thus [x,y] is of rank  $< \alpha$ . That is,  $M \in \mathcal{B}_{<\alpha}$ .

Since every subinterval of rank  $\leq \alpha$  is a finite sum of  $\mathbb{Z}$ -sums of intervals of rank  $< \alpha$ , we are done.

# 3 Decidability of the rank

**Definition 10.** Let M be a linear order and  $x \in M$ .

We define the convex equivalence relation  $\sim_{\alpha} := \sim_{\mathcal{B}_{<\alpha}}$ , and  $[x]_{\alpha} := [x]_{\mathcal{B}_{<\alpha}}$  (that is,  $[x]_{\alpha}$  is the largest  $\mathcal{B}_{<\alpha}$ -subinterval containing x in M).

**Lemma 5.** Let M be a linear order. Let  $P, L, R \subseteq M$  be relations, such that:

- P represents  $\sim_{\alpha}$  on M.
- L is such that  $x \in L$  iff  $[x]_{\alpha} \in \mathcal{L}_{\leq \alpha}$ .
- R is such that  $x \in R$  iff  $[x]_{\alpha} \in \mathcal{R}_{<\alpha}$ .

Then for some linear order I there exists a decomposition  $M = \sum_{i \in I} M_i$  such that  $M_i \in \mathcal{B}_{<\alpha}$  for all  $i \in I$ ,  $M_i$  is monochromatic with respect to P, L and R.

Furthermore, let  $\tau_i$  be the n-type of  $M_i, p_i, q_i, r_i$  in  $\mathbf{MSO}[p, \ell, r]$ , where  $p_i = 1_{M_i \subseteq P}, \ q_i = 1_{M_i \subseteq L}$  and  $r_i = 1_{M_i \subseteq R}$ . Then the following hold

• if i has a successor,  $p(\tau_i) \neq p(\tau_{i+1})$ 

• if i has a successor, either  $r(\tau_i) = 0$  or  $\ell(\tau_{i+1}) = 0$ 

*Proof.* Take  $I = M/\sim_{\alpha}$ .

Then  $M = \sum_{i \in I} M_i$  where  $M_i$  is the  $\sim_{\alpha}$ -equivalence class of i.

Then  $M_i$  is monochromatic with respect to P, L and R.

The only thing left to prove is the last two conditions. The first follows from the fact that P represents  $\sim_{\alpha}$ .

The second follows because if it were not the case, then  $M_i$  and  $M_{i+1}$  would be the same  $\sim_{\alpha}$ -equivalence class.

**Lemma 6.** Let I be a linear order. Let  $n \in \mathbb{N}$ . Let  $p, \ell, r$  be boolean variables. Let  $\tau_i$  be an assignment of satisfiable n-types in  $\mathbf{MSO}[p, \ell, r]$  for all  $i \in I$ . Assume that

- if i has a successor,  $p(\tau_i) \neq p(\tau_{i+1})$
- if i has a successor, either  $r(\tau_i) = 0$  or  $\ell(\tau_{i+1}) = 0$

Then there exists a linear order M and  $P, L, R \subseteq M$  such that:

- P represents  $\sim_{\alpha}$  on M.
- L is such that  $x \in L$  iff  $[x]_{\alpha} \in \mathcal{L}_{<\alpha}$ .
- R is such that  $x \in R$  iff  $[x]_{\alpha} \in \mathcal{R}_{<\alpha}$ .

such that for all  $i \in I$ ,  $M_i$  is a  $\sim_{\alpha}$ -equivalence class of M, and is thus monochromatic with respect to P, L and R.

Furthermore, the n-type of  $M_i, p_i, q_i, r_i$  in  $\mathbf{MSO}[p, \ell, r]$  is  $\tau_i$ , where  $p_i = 1_{M_i \subset P}$ ,  $q_i = 1_{M_i \subset L}$  and  $r_i = 1_{M_i \subset R}$ ,

*Proof.* Since  $\tau_i$  is satisfiable, we can take  $M_i$  to be a linear order of *n*-type  $\tau_i$  such that:

- If  $\ell(\tau_i) = r(\tau_i) = 1$ , then  $M_i \in \mathcal{L}_{<\alpha} \cap \mathcal{R}_{<\alpha}$ .
- If  $\ell(\tau_i) = 1$  and  $r(\tau_i) = 0$ , then  $M_i \in \mathcal{L}_{\leq \alpha} \mathcal{R}_{\leq \alpha}$ .
- If  $\ell(\tau_i) = 0$  and  $r(\tau_i) = 1$ , then  $M_i \in \mathcal{R}_{\leq \alpha} \mathcal{L}_{\leq \alpha}$ .
- If  $\ell(\tau_i) = r(\tau_i) = 0$ , then  $M_i \in \mathcal{B}_{<\alpha} (\mathcal{L}_{<\alpha} \cup \mathcal{R}_{<\alpha})$ .

Let  $M = \sum_{i \in I} M_i$ .

By definition each  $M_i$  is in  $\mathcal{B}_{<\alpha}$ . We need to prove that each  $M_i$  is a largest  $\mathcal{B}_{<\alpha}$ -subinterval in M.

On the contrary, suppose that there exist  $i' \neq i$  such that  $[M_i, M_{i'}] \in \mathcal{B}_{<\alpha}$ . WLOG,  $M_i < M_{i'}$ .

Since I is scattered, take some  $i \le a < b \le i'$  such that there is no element between a and b in I.

Then  $M_a \in \mathcal{R}_{<\alpha}$  and  $M_b \in \mathcal{L}_{<\alpha}$ , in contradiction.

**Lemma 7.** Over countable linear orders with interpretations of P, L and R as above, the properties  $\mathbf{hrank}_{\mathbf{Q}}(\cdot) \leq \alpha$ ,  $\mathbf{hrank}_{\mathbf{Q}}(\cdot) < \alpha$  and  $\mathbf{hrank}_{\mathbf{Q}}(\cdot) = \alpha$  over subintervals are all expressible in  $\mathbf{MSO}[P, L, R]$ .

*Proof.* For  $\mathbf{hrank}_{\mathbf{Q}}\left(\cdot\right) \leq \alpha$  and  $\mathbf{hrank}_{\mathbf{Q}}\left(\cdot\right) < \alpha$ , we can use the previous lemmas.

For  $\mathbf{hrank}_{\mathbf{O}}(\cdot) = \alpha$ , we can use the previous two.

**Lemma 8.** There exists a global computable function  $f : \mathbb{N} \to \mathbb{N}$  such that for all  $n \in \mathbb{N}$ ,  $\mathbf{type}_n \left[ \mathcal{H}_{f(n)+1} \right] = \mathbf{type}_n \left[ \mathcal{H}_{f(n)} \right]$ .

Equivalently, every linear order of finite rank is n-equivalent to some linear order of rank  $\leq f(n)$ .

*Proof.* Since there exist only a finite number of n-types, and the  $\omega$ -sequence  $\{\mathbf{type}_n [\mathcal{H}_k]\}_{k\in\omega}$  is monotone, it must stabilize at some point.

This point is computable as a function of n, because  $\mathbf{type}_n[\mathcal{H}_k]$  is computable for every finite k.

**Lemma 9.** There exist global computable functions  $a, b : \mathbb{N} \to \mathbb{N}$  such that for all  $n, c_1, c_2 \in \mathbb{N}$  such that  $c_1, c_2 \geq a(n)$  and  $c_1 \equiv c_2 \mod b(n)$ ,

$$\mathbf{type}_{n}\left[\mathcal{H}_{c_{1}}\right]=\mathbf{type}_{n}\left[\mathcal{H}_{c_{2}}\right]$$

Equivalently, the sequence  $\{\mathbf{type}_n [\mathcal{H}_k]\}_{k\in\omega}$  is ultimately periodic for all  $n\in\mathbb{N}$ . Furthermore, the starting point and the period itself can be computed as a function of n.

*Proof.* Let  $n \in \mathbb{N}$ .

Since there exist only a finite number of possible sets of n-types, there exist (and can be computed) some a(n) > f(n), a(n) + b(n) such that

$$\mathbf{type}_n\left[\mathcal{H}_{a(n)}
ight] = \mathbf{type}_n\left[\mathcal{H}_{a(n)+b(n)}
ight]$$

We shall prove by induction that for all  $c \ge a(n) + b(n)$ ,

$$\mathbf{type}_{n}\left[\mathcal{H}_{c}
ight]=\mathbf{type}_{n}\left[\mathcal{H}_{c+b(n)}
ight]$$

This will complete the proof.

The base case c = a(n) has been proven in the beginning.

Suppose the induction hypothesis holds for c.

Let M be of rank c+1.

Write  $M = \sum_{i \in I} M_i$  where  $\mathbf{hrank}_{\mathbf{Q}}(M_i) < c + 1$ , and  $\mathbf{hrank}_{\mathbf{Q}}(M_i) = c$  infinitely many times.

By the induction hypothesis, if  $\mathbf{hrank_Q}(M_i) = c$ , we can find  $N_i \equiv_n M_i$  with  $\mathbf{hrank_Q}(N_i) = c + b(n)$ . Setting  $N_i := M_i$  for all other i, we conclude that  $N := \sum_{i \in I} N_i$  is n-equivalent to M.

However, clearly  $\mathbf{hrank}_{\mathbf{Q}}(N) = c + b(n) + 1$ . So overall,

$$\mathbf{type}_n\left[\mathcal{H}_{c+1}
ight]\subseteq\mathbf{type}_n\left[\mathcal{H}_{c+b(n)+1}
ight]$$

Conversely, suppose M is of rank c + b(n) + 1. Write  $M = \sum_{i \in I} M_i$  where  $\mathbf{hrank}_{\mathbf{Q}}(M_i) < c + b(n) + 1$ , and  $\mathbf{hrank}_{\mathbf{Q}}(M_i) = c + b(n)$  infinitely many times.

By the induction hypothesis, we can find for all i such that  $\mathbf{hrank}_{\mathbf{Q}}(M_i) = c + b(n)$  some  $N_i \equiv_n M_i$  with  $\mathbf{hrank}_{\mathbf{Q}}(N_i) = c$ . Furthermore, since  $c \geq a(n) > f(n)$ , we can find  $N_i \equiv_n M_i$  with  $\mathbf{hrank}_{\mathbf{Q}}(N_i) \leq f(n) < c$  for all other i.

We conclude that  $N := \sum_{i \in I} N_i$  is *n*-equivalent to M. However, clearly  $\mathbf{hrank}_{\mathbf{Q}}(N) = c + 1$ . So overall,

$$\mathbf{type}_{n}\left[\mathcal{H}_{c+b(n)+1}
ight]\subseteq\mathbf{type}_{n}\left[\mathcal{H}_{c+1}
ight]$$

So we have proven the induction step, and the lemma follows.

**Lemma 10.** Let  $n \in \mathbb{N}$ , and let  $\alpha \geq \omega$  be an ordinal. Then,

$$ext{type}_n \left[ \mathbf{Q}^{=lpha} 
ight] = igcup_{c < b(n)} ext{type}_n \left[ \mathcal{H}_{c+b(n)} 
ight]$$

In particular,  $\mathbf{type}_n[\mathbf{Q}^{=\alpha}]$  can be computed, and is independent of the choice  $\alpha \geq \omega$ .

Proof. TBC. 
$$\Box$$

Corollary 1. The following sequences stabilize at f(n):

- $\mathbf{type}_n\left[\mathcal{H}_{\alpha}\right]$
- type<sub>n</sub>  $[\mathcal{B}_{<\alpha}]$
- type<sub>n</sub>  $[\mathcal{L}_{<\alpha}]$
- type<sub>n</sub>  $[\mathcal{R}_{<\alpha}]$
- type<sub>n</sub>  $[\mathcal{L}_{<\alpha} \mathcal{R}_{<\alpha}]$
- type<sub>n</sub>  $[\mathcal{R}_{<\alpha} \mathcal{L}_{<\alpha}]$
- type<sub>n</sub>  $[\mathcal{B}_{<\alpha} (\mathcal{L}_{<\alpha} \cup \mathcal{R}_{<\alpha})]$

*Proof.* The corollary is false and should be fixed.

**Theorem 1.** There is a an algorithm solving satisfiability for MSO[P, L, R] over countable linear orders, given an oracle which solves the satisfiability problem for MSO over countable linear orders.

*Proof.* By the decomposition theorem, there exists a translation, that given an  $\mathbf{MSO}[P,L,R]$  formula  $\varphi$  of quantifier-depth n. outputs an  $\mathbf{MSO}[\{X_{\tau}\}_{\tau}]$  formula  $\psi$ .

Let  $P_L, Q_L, R_M$  be the interpretations of P, L, R on M. Then

$$M, P := P_L, L := Q_L, R := R_L \models \varphi \iff I, \{X_\tau := I_\tau\}_\tau \models \psi$$

Where  $I_{\tau} = \{i \in I : M_i \models \tau\}$  for every *n*-type  $\tau$ .

Let T be the set of n-types in  $\mathbf{MSO}[p,\ell,r]$  which satisfy  $\ell(\tau) = 1 \iff \tau \in \mathcal{L}_{<\alpha}$  and  $r(\tau) = 1 \iff \tau \in \mathcal{R}_{<\alpha}$ .

Let  $S = \{(\tau_1, \tau_2) : p(\tau_1) \neq p(\tau_2) \land (r(\tau_1) = 0 \lor \ell(\tau_2) = 0)\}.$ 

Then T and S can be calculated using the oracle.

Then  $\psi$  is an MSO[T, S] formula.

Then we define an  $\mathbf{MSO}[p,\ell,r]$  formula  $\psi'$  as follows:

 $\psi'$  claims that there exists a partition (with possible empty sets)  $\{Y_\tau\}_\tau$  of I such that

- Every  $i \in I$  is in some  $Y_{\tau}$  for  $\tau \in T$ .
- If i' = i + 1 in I, then for some  $(\tau_1, \tau_2) \in S$ ,  $i \in Y_{\tau_1}$  and  $i' \in Y_{\tau_2}$ .

Now we claim that  $\varphi$  is satisfiable in some linear order, iff  $\psi'$  is satisfiable in some linear order.

Suppose  $\varphi$  is satisfiable in some linear order M.

Take a decomposition  $M = \sum_{i \in I} M_i$  as in lemma 2.

Then  $\psi$  holds over the assignment  $X_{\tau} := I_{\tau}$ . But by lemma 2, this assignment satisfies the condition required for  $\psi'$  to hold. Then  $\psi'$  holds over I.

Conversely, suppose  $\psi'$  holds in I.

Let  $X_{\tau} := Z_{\tau}$  be the assignment that is guaranteed by  $\psi'$ .

Let  $tau_i$  be the unique  $\tau$  such that  $i \in Z_{\tau}$ .

Then the conditions for lemma 3 are guaranteed.

Thus, take M as in lemma 3. Then  $\psi$  holds over I when we set  $X_i := Z_{\tau}$ . But  $Z_{\tau} = I_{\tau}$  for all  $\tau$ , so  $\varphi$  holds over M.
